Type and Clock Checking in $Lustre^*$ (Draft)

L2C team, System Software and Software Engineering Laboratory Department of Computer Science and Technology, Tsinghua University

December 18, 2018

1 Introduction

A type system keeps track of the types of variables and, in general, of the types of all expressions in a program. Type systems are used to determine whether programs are well behaved. A statically type checking process is performed, by a type checker, to prevent unsafe and ill behaved programs from ever running. A program that passes the type checker is said to be well typed; otherwise, it is ill typed.

The type checking in this document includes two parts of statically checking for the $Lustre^*$ language, the source language in the L2C project. One is for the conventional type checking, and the other is for the clock checking specific to a Lustre-like synchronous data-flow language. The abstract syntax of $Lustre^*$, produced by parsing, is specified in the next section. The type system for the conventional type checking and the clock checking, defined on this abstract syntax, are presented in Section 3 and Section 4 respectively.

2 Abstract Syntax of Lustre*

2.1 Program

```
 \langle program \rangle ::= \{ \langle one\_decl \rangle \} 
 \langle one\_decl \rangle ::= \langle type\_decl \rangle 
 | \langle const\_decl \rangle 
 | \langle node\_decl \rangle
```

2.2 Type Declaration

```
\langle type\_decl \rangle ::= (IDENT, \langle kind \rangle)
```

```
\langle kind \rangle ::= Short
                               (* integer types, signed 16 bits *)
              UShort
                                (* integer types, unsigned 16 bits *)
             Int
                            (* integer types, signed 32 bits *)
             UInt
                             (* integer types, unsigned 32 bits *)
             Float
                              (* floating-point types, 32 bits *)
             Real
                             (* floating-point types, 64 bits *)
             Bool
                             (* bool types *)
             Char
                              (* char types *)
             Array(\langle kind \rangle, IntConst(INTEGER))
             Struct(\langle fieldlist \rangle)
             Enum(\langle identlist \rangle)
\langle fieldlist \rangle ::= (IDENT, \langle kind \rangle)^*
\langle identlist \rangle ::= (IDENT)^*
2.3
         Const Declaration
\langle const\_decl \rangle ::= (IDENT, \langle kind \rangle, \langle const \rangle)
\langle const \rangle ::= ShortConst(INTEGER)
                                                       (* integer constants, signed 16 bits *)
                                                         (* integer constants, unsigned 16 bits *)
             | UshortConst(INTEGER)|
               IntConst(INTEGER)
                                                    (* integer constants, signed 32 bits *)
               UintConst(INTEGER)
                                                      (* integer constants, unsigned 32 bits *)
                                                       (* char constants *)
               CharConst(INTEGER)
                                                   (* floating-point constants, 32 bits *)
               FloatConst(FLOAT)
               RealConst(REAL)
                                                (* floating-point constants, 64 bits *)
               BoolConst(\langle bool \rangle)
                                               (* bool constants *)
               ArrayConst(\langle const \ list \rangle)
                                                        (* array constants *)
               ConstructConst(\langle field\_const\_list \rangle)
                                                                     (* struct constants *)
               EnumConst(IDENT, \langle kind \rangle)
                                                             (* enum constants *)
              | ID(IDENT)  (* to define other constants by a constant identifier *)
\langle bool \rangle ::= TRUE \mid FALSE
\langle const | list \rangle ::= \langle const \rangle^*
\langle field\ const \rangle ::= (IDENT, \langle const \rangle)
\langle field\ const\ list \rangle ::= \langle field\ const \rangle^*
2.4
         Node/Function Declaration
\langle node \ decl \rangle ::= (\langle funcType \rangle, \langle modifier \rangle, IDENT, \langle params \rangle, \langle returns \rangle, \langle body \rangle)
                                               //node or function declareation
\langle funcType \rangle ::= node \mid function
```

 $\langle modifier \rangle ::= main \mid notMain$

```
\langle params \rangle ::= \langle var \ decl \rangle^*
\langle returns \rangle ::= \langle var\_decl \rangle^*
\langle var\_decl \rangle ::= VDecl(IDENT, \langle kind \rangle)
                    | WhenVDecl(IDENT, \langle kind \rangle, \langle ck \rangle)
\langle ck \rangle ::= (TRUE, IDENT) \mid (FALSE, IDENT) \quad (* IDENT is a bool identifier *)
          | (IDENT, IDENT) (* right IDENT: an enum var, left IDENT: a value *)
\langle body \rangle ::= (\langle locals \rangle, \langle equation\_list \rangle)
\langle locals \rangle ::= \langle var \ decl \rangle^*
\langle equation | list \rangle ::= \langle equation \rangle^*
\langle equation \rangle ::= Equation(\langle lhs \rangle, \langle expr \rangle)
\langle lhs \rangle ::= \langle lhs\_id \rangle^*
\langle lhs \ id \rangle ::= IDENT
\langle expr \rangle ::= Econst(\langle atom\_const \rangle)
                Evar(IDENT)
                ListExpr(\langle expr\_list \rangle)
                                                           (* list expression *)

```

3 Type System for type checking

3.1 Type expressions

3.1.1 Basic types

A basic type expression can be defined by the syntax shown as follows.

```
< type > ::= < scalar\_type >
                                                                          scalar types
                       < array\_type >
                                                                          array types
                       <\!struct\_type\!>
                                                                          struct types
                                                                          enum types
                                                                          any type
                  ::= ushort
                                                                          integer types, unsigned 16 bits
< scalar\_type >
                       short

                 ::= enum(<ident> \{, <ident> \})
< enum type >
                                                                          enum type
```

where the <ident> shares the definition in Section 2.5.

3.1.2 Compound types

We introduce two kinds of compound types.

A product type expression $A_1 \times A_2 \times ... \times A_n$ is the type of tuples of values with the first component of type expression A_1 , the second component of type expression A_2 , ..., and the nth component of type expression A_n . It is possible that n=0, where it means a nil list of type. We often use $A_1 :: A_2 :: ... :: A_n$, instead of $A_1 \times A_2 \times ... \times A_n$, in the case for a list of expressions (not a list of parameters).

A node/function type expression $A_1 \times A_2 \times ... \times A_n \to B_1 \times B_2 \times ... \times B_m$ is the type expression of nodes or functions with the input parameter list of type $A_1 \times A_2 \times ... \times A_n$, and the output parameter list of type $B_1 \times B_2 \times ... \times B_m$.

3.2 Typing environment

A typing environment associates type expressions to variables and has the form

$$\mathcal{E} ::= [x_1 : A_1, A_2 : A_2, ..., x_n : A_n]$$

where $x_i \neq x_j$ for all i and j, satisfying $i \neq j$ and $(1 \leq i, j \leq n)$.

We use C, T and F to denote a global const block typing environment, a global type block typing environment and a local function/node typing environment respectively. In some cases, we use F_{id} to denote a particular local typing environment specific to the context of a node/function identified by id.

3.3 Judgements

- $\mathcal{E} \vdash e : A$, implies that, under the the well-formed typing environment \mathcal{E} , the expression e is well-typed and has the type A. Here, \mathcal{E} can be ϕ , \mathcal{C} , \mathcal{T} or \mathcal{F} .
- $\mathcal{E} \vdash D$, implies that, under the the well-formed typing environment \mathcal{E} , the program component D is well-typed. Here, \mathcal{E} can be ϕ , \mathcal{C} , \mathcal{T} or \mathcal{F} .
- $\mathcal{E} \vdash \diamond$, means that \mathcal{E} is a well-formed typing environment. Here, \mathcal{E} can be ϕ , \mathcal{C} , \mathcal{T} or \mathcal{F} . We also use some abbreviations to denote the well-formedness for two or more typing environments. For example, \mathcal{C} , $\mathcal{T} \vdash \diamond$, means that both \mathcal{C} and \mathcal{T} are well-formed typing environments respectively.
- \mathcal{C} , $\mathcal{T} \vdash e : A$, implies that, under the well-formed typing environments \mathcal{C} and \mathcal{T} , the expression e is well-typed and has the type A.
- $C, T \vdash D$, implies that under the well-formed typing environments C and T, the program component D is well-typed.
- \mathcal{C} , \mathcal{T} , $\mathcal{F} \vdash e : A$, implies that, under the well-formed typing environments \mathcal{C} , \mathcal{T} and \mathcal{F} , the expression e is well-typed and has the type A.
- C, T, $F \vdash D$, implies that under the well-formed typing environments C, T and F, the program component D is well-typed.

3.4 Rules used for the conventional type checking based on the abstract syntax of $Lustre^*$

3.4.1 Common

$$\frac{}{\phi \vdash \diamond} \; (\text{Env} \; \phi) \qquad \qquad \frac{\mathcal{E} \vdash \diamond \qquad x : A \in \mathcal{E}}{\mathcal{E} \vdash x : A} \; (\text{Env TVal})$$

$$\frac{\mathcal{E}' \vdash \diamond \qquad x \notin dom(\mathcal{E}') \qquad \mathcal{E} = \mathcal{E}' \cup \{x : A\}}{\mathcal{E} \vdash \diamond} \text{ (Env Wellty)}$$

$$\frac{\mathcal{E}' \vdash e : A \qquad y \not\in dom(\mathcal{E}') \qquad \mathcal{E} = \mathcal{E}' \cup \{y : A'\}}{\mathcal{E} \vdash e : A} \text{ (Env Ext)}$$

$$\frac{\mathcal{C} \vdash \diamond \qquad \mathcal{T} \vdash \diamond}{\mathcal{C}, \mathcal{T} \vdash \diamond} \text{ (EnvCT Com)} \qquad \frac{\mathcal{C} \vdash \diamond \qquad \mathcal{T} \vdash \diamond}{\mathcal{C}, \mathcal{T}, \mathcal{F} \vdash \diamond} \text{ (EnvCTF Com)}$$

$$\frac{\mathcal{C} \vdash e : A \qquad \mathcal{T} \vdash \diamond}{\mathcal{C}, \mathcal{T} \vdash e : A} \text{ (EnvC Ext1)} \qquad \frac{\mathcal{C} \vdash D \qquad \mathcal{T} \vdash \diamond}{\mathcal{C}, \mathcal{T} \vdash D} \text{ (EnvC Ext2)}$$

$$\frac{\mathcal{C}, \mathcal{T} \vdash e : A}{\mathcal{C}, \mathcal{T}, \mathcal{F} \vdash e : A} \text{ (EnvCNT Ext1)} \qquad \frac{\mathcal{C}, \mathcal{T} \vdash D}{\mathcal{C}, \mathcal{T}, \mathcal{F} \vdash D} \text{ (CEnvNT Ext2)}$$

Program

4 Type System for clock checking

Clock calculus deals with the correctness and consistency of clock definitions and usage within and among function calls. Clock checker checks the validity of the clock operators that manipulate multiple clocks, based on the rules of clock calculus.

4.1 Clocks

4.1.1 Basic clock expressions

In a Lustre* program, each node/function has a base clock. This is the clock used when the node/function is called. Each of arguments of the node/function may also be associated with a different clock when it is called. The base clock of the Main node is the reference clock of the whole program used directly or indirectly by all of the clocks derived in its call tree. A basic clock is expressed as follows.

The expression "clock on ck" performs the sampling of the clock ck, i.e. deriving a new clock based on ck, using a variable or constant name, or the negation of such an identifier, or a pattern matching. In the first two cases, the identifier must has a bool data type. In the latter case, the identifier must has an enum data type, and the pattern part must refer to one of the item of this data type.

The expression "clock on ck is used to realize the When operator. Here, clock has a higher clock rate, and the derived (or sampled) clock from the expression "clock on ck" has a lower clock rate because those clock cycles, when c is False or does not match a specific enum item , are skipped.

4.1.2 Compound clock expressions

The compound clock expression $ck_1 :: ck_2 :: ... :: ck_n$ is the clock of tuples of expressions with the first component of clock expression ck_1 , the second component of clock expression ck_2 , ..., and the *n*th component of clock expression ck_n . It is possible that n = 0, where it means a *nil* list of clock expressions.

4.2 Clock environments

A local clock environment \mathcal{H} associates clocks to variables and has the form

$$\mathcal{H} ::= [x_1 : ck_1, x_2 : ck_2, ..., x_n : ck_n]$$

where $x_i \neq x_j$ for $i \neq j$.

In some cases, we use \mathcal{H}_{id} to denote a particular local clock environment specific to the context of a node/function identified by id.

4.3 Judgements

- $\mathcal{H} \vdash e : ck$, implies that, under the clock environment \mathcal{H} , the expression e is well-clocked and has the clock ck.
- $\mathcal{H} \vdash D$, implies that under the clock environment \mathcal{H} , the program component D is well-clocked.
- $\mathcal{H} \vdash \diamond$, implies that the clock environment \mathcal{H} is well-defined.

4.4 Rules for the clock calculus on the abstract syntax of well-typed $Lustre^*$

In L2C project, the clock checking is performed immediately after the conventional type checking. So it is supposed that the type system for the clock checking be designed for a well typed program, that is, a program p satisfying $\phi \vdash p$ as is derived by the very last rule in Section 3.4.9. The type system for the clock checking is given by defining the rules for the clock calculus as follows.

4.4.1 Common

$$\frac{}{\phi \vdash \diamond} \text{ (Env } \phi) \qquad \frac{\mathcal{H}' \vdash \diamond \qquad x \notin dom(\mathcal{H}') \qquad \mathcal{H} = \mathcal{H}' \cup \{x : x_ck\}}{\mathcal{H} \vdash \diamond} \text{ (Env Wellck)}$$

$$\frac{\mathcal{H} \vdash \diamond \qquad x : x_ck \in \mathcal{H}}{\mathcal{H} \vdash x : x_ck} \text{ (Env CkVal)}$$

4.4.2 Initialization of Clock Environments

```
nd = (funcType, modifier, id, parameters, returns, body)
                                     body = (locals, eq\_list)
                                VDecl(x,t) \in parameters++returns++locals
                       x \notin dom(\mathcal{H}'_{id}) \qquad \mathcal{H}_{id} = \mathcal{H}'_{id} \cup \{x : base\}\mathcal{H}_{id} \vdash \diamond
                                                                                             — EnvInit noWhen
             nd = (funcType, modifier, id, parameters, returns, body)
                                       body = (locals, eq\_list)
              VDecl(x, t') \in parameters \lor WhenVDecl(x, t', c') \in parameters
      c = (b, x)
                          When VDecl((y, t, c) \in parameters + + returns \quad x \neq y
      \frac{y \notin dom(\mathcal{H'}_{id}) \qquad \mathcal{H'}_{id} \vdash x : x\_ck \qquad \mathcal{H}_{id} = \mathcal{H'}_{id} \cup \{y : x\_ck \ on \ c\}}{\mathcal{H}_{id} \vdash \diamond}  EnvInit hasWhenPR
              nd = (funcType, modifier, id, parameters, returns, body)
                              body = (locals, eq\_list) \mathcal{H'}_{id} \vdash \diamond
VDecl(x, t') \in parameters + +locals \lor When VDecl(x, t', c') \in parameters + +locals
                   c = (b, x) \qquad \textit{WhenVDecl}(y, t, c) \in \textit{locals} \qquad x \neq y
       \frac{y \notin dom(\mathcal{H'}_{id}) \qquad \mathcal{H'}_{id} \vdash x : x\_ck \qquad \mathcal{H}_{id} = \mathcal{H'}_{id} \cup \{y : x\_ck \ on \ c\}}{\mathcal{H}_{id} \vdash \diamond} \qquad \qquad \text{EnvInit hasWhenL}
```

4.4.3 Temporal and Clock Expressions

$$e = Epre(expr) \qquad expr = e_1 :: e_2 :: ... :: e_n \\ \mathcal{H} \vdash \diamond \qquad \mathcal{H} \vdash e_1 : ck_1 \quad \mathcal{H} \vdash e_2 : ck_2 \quad ... \quad \mathcal{H} \vdash e_n : ck_n \\ \mathcal{H} \vdash e : ck_1 :: ck_2 :: ... :: ck_n \\ \mathcal{H} \vdash e : ck_1 :: ck_2 :: ... :: ck_n \\ \mathcal{H} \vdash e : ck_1 :: ck_2 :: ... :: ck_n \\ e = Efby(expr, IntConst(k), expr') \\ expr = e_1 :: e_2 :: ... :: e_n \qquad expr' = e'_1 :: e'_2 :: ... :: e'_n \\ \mathcal{H} \vdash \diamond \qquad \mathcal{H} \vdash e_1 : ck_1 \quad \mathcal{H} \vdash e_2 : ck_2 \quad ... \quad \mathcal{H} \vdash e_n : ck_n \\ \mathcal{H} \vdash e'_1 : ck_1 \quad \mathcal{H} \vdash e'_2 : ck_2 \quad ... \quad \mathcal{H} \vdash e'_n : ck_n \\ \mathcal{H} \vdash e'_1 : ck_1 \quad \mathcal{H} \vdash e'_2 : ck_2 \quad ... \quad \mathcal{H} \vdash e'_n : ck_n \\ \mathcal{H} \vdash e : ck_1 :: ck_2 :: ... :: ck_n \\ \mathcal{H} \vdash e'_1 : ck_1 \quad \mathcal{H} \vdash e'_2 : ck_2 \quad ... \quad \mathcal{H} \vdash e'_n : ck_n \\ \mathcal{H} \vdash e'_1 : ck_1 \quad \mathcal{H} \vdash e'_2 : ck_2 \quad ... \quad \mathcal{H} \vdash e'_n : ck_n \\ \mathcal{H} \vdash e'_1 : ck_1 \quad \mathcal{H} \vdash e'_2 : ck_2 \quad ... \quad \mathcal{H} \vdash e'_n : ck_n \\ \mathcal{H} \vdash e'_1 : ck_1 \quad \mathcal{H} \vdash e'_2 : ck_2 \quad ... \quad \mathcal{H} \vdash e'_n : ck_n \\ \mathcal{H} \vdash e'_1 : ck_1 \quad \mathcal{H} \vdash e'_2 : ck_2 \quad ... \quad \mathcal{H} \vdash e'_n : ck_n \\ \mathcal{H} \vdash e : ck_1 :: ck_2 :: ... :: ck_n \quad c_n \quad c = (b, x) \\ \mathcal{H} \vdash \diamond \quad \mathcal{H} \vdash x : ck \quad \mathcal{H} \vdash e_1 : ck_1 \quad \mathcal{H} \vdash e_2 : ck_2 \quad ... \quad \mathcal{H} \vdash e_n : ck_n \\ \mathcal{H} \vdash e : ck_1 :: ck \quad \mathcal{H} \vdash e_1 : ck_1 \quad \mathcal{H} \vdash e_2 : ck_2 \quad ... \quad \mathcal{H} \vdash e_n : ck_n \\ \mathcal{H} \vdash e : ck_1 :: ck :: ck_2 :: ... :: ck_n ::$$

4.4.4 Call Expressions

```
e = ApplyExpr(id, args\_list)
